INTRODUCTION

Pregnancy is one of the most essential stages of a woman's life and is associated with fundamental lifestyle change. Physiological, anatomical, and biochemical changes in pregnant women cause stress and decrease their quality of life (QoL). According to studies, discomfort and problems during pregnancy reduce a woman's ability to perform daily roles in life and cause many changes in people's physical, mental, and social issues, all of which can disrupt the QoL of pregnant women.

The quality of sleep has a significant impact on the QoL and is one of the main foundations of health. Sleep in pregnant women is generally disrupted as a consequence of numerous factors. Sleep problems is one of the most prevalent complaints during pregnancy. The most common type of sleep disorder in pregnancy is insomnia. Most sleep disorders during pregnancy are experienced by expectant mothers in the third trimester and closer to the end of pregnancy. Insomnia, with changes in a woman's immune system, such as changes in the level of C-reactive protein and cytokines, can have adverse consequences such as premature birth, reduced pain tolerance, blood pressure disorders, mental health problems, low birth weight, glucose tolerance disorders and depression during pregnancy and postpartum are related.

Despite the apparent reduction of sleep quality in pregnancy, the mechanisms and solutions to this problem are still unknown. Sleeping pills are the first recommended treatment for chronic insomnia, which has severe side effects for pregnant women. Therefore, complementary and alternative therapies such as acupressure, acupuncture, aromatherapy, reflexology, and exercise have been followed in many studies.

ABSTRACT

Aims: As one of the most critical periods in women's lives, pregnancy affects their physical, mental, and functional conditions. These changes can affect the quality of life and sleep of pregnant women. The main purpose of this study is to investigate the effect of pilates exercises on 150 young pregnant women between the ages of 20-40.

Methods: This randomized double-blind clinical trial study was done between September 2023 and March 2024, including 60 pregnant women in case group and 90 control subjects of similar age and body mass index (BMI). This study investigated the effect of 12 weeks of pilates exercises on the quality of women's sleep and life. Quality of life was measured by the short-form 36 (SF-36) and quality of sleep by the Pittsburgh Sleep Quality Index (PSQI). People were randomly divided into intervention and control groups. Pregnant women in the intervention group were required to participate in two pilates sessions per week for 12 weeks from the 20th week of pregnancy.

Results: Our results found that quality of life levels were statistically significant higher than case group after intervention compared to control group (p<0.05; 67.19 vs. 54.94). Also, a statistically significant association between the case and control regarding quality of sleep (p<0.05; 5.41 vs. 6.77).

Conclusion: It is concluded that performing moderate-intensity pilates exercises for 12 weeks in the last months of pregnancy can increase sleep quality and life.

Keywords: Pregnant women, pilates, sleep quality, quality of life, women's life
QoL includes different aspects of health and physical, mental, and social comfort of people. Each dimension of quality of life has two subjective and objective elements that can be measured. Moderate physical activity can improve a person’s QoL by affecting physical and mental health. Regarding the necessity of physical activity in women with uncomplicated pregnancies, the American College of Obstetricians and Gynecologists (ACOG) recommends exercising at moderate intensity for 20–30 minutes a day during pregnancy on most or all days of the week. Pilates exercise is a prevalent physical activity preferred by pregnant women. ACOG recommends modified pilates during pregnancy. By saving and increasing the energy level, pilates improves the body’s strength, stability, and flexibility and is beneficial in musculoskeletal pain, stress and fatigue reduction, creating relaxation, and curing sleep health.

Despite the many advantages of pilates and suggestions for doing this exercise during pregnancy, its benefits are still debated, and more relevant research is needed. Considering the existing uncertainties about the effect of pilates on the quality of sleep and life of pregnant women, the present study was conducted to investigate the effect of pilates on the outcomes expressed in pregnant women.

**METHODS**

This randomized double-blind clinical trial was conducted on patients between September 2023 and March 2024. Local ethics committee approval was obtained from Istanbul Medipol University Non-invasive Clinical Researches Ethics Committee (Date: 12.10.2023 Decision No: 839). All procedures were carried out in accordance with the ethical rules and the principles of the Declaration of Helsinki.

The study did not include women with a ban on exercise during pregnancy. Women who had chronic diseases, multiple pregnancies and were not between 20-40 years old were also excluded from the study.

Pilates exercises for the case group started from the 20th week of pregnancy. At the beginning of the research gestational age was determined through ultrasound. Exercises were performed in the gym under the supervision of a certified pilates instructor and based on safe pilates exercises (modified plank, banana leg, and modified roll-up) during pregnancy. The intervention was conducted with moderate intensity for 12 weeks and twice a week. Each pilates training session, including 8-10 strength exercises, was done for 30 minutes. The trainer controlled the research participants’ attendance list to ensure the exercises’ regularity. The women of the case group were followed up regularly through phone calls every week. Women in the control group also received usual care.

This study’s data collection tools included a demographic profile questionnaire, the Pittsburgh Sleep Quality Index (PSQI), and short-form 36 (SF-36) questionnaire. To investigate the effect of pilates exercise, sleep quality and life quality questionnaires were completed by women in both case and control groups. PSQI is an international standard instrument validated in several studies. The reliability and validity of the Turkish version of this questionnaire were checked and confirmed. The total score of this index is between 0–21, and the total score is greater than 6, showing the inappropriateness of sleep quality.

The quality of life index SF-36 is also an international standard instrument whose Turkish version validated in previous study. This questionnaire consists of 8 sections, which include physical function (10 items), physical pain (2 items), social function (2 items), mental health (5 items), general health (5 items), vitality (4 items), physical problems (4 items) and mental problems (3 items) and includes 36 questions in total. Therefore, the mentioned questionnaire tries to express a comprehensive assessment of the individual’s current health status to the researcher by examining the individual’s health status in 8 dimensions. The total score of this index is between 0-100.

**Statistical Analysis**

The study used mean (M) and standard deviation (SD) to report the descriptive statistics of data. The categorical variables described by number and percent and analyzing by Chi-Squared test. To compare the data between groups, the Independent t-test was employed, which is appropriate for normal distributions. SPSS software (version 21.0, SSPS Inc., Chicago, IL, USA) was employed for statistical analysis. The threshold for statistical significance was set at a p-value of less than 0.05.

**RESULTS**

This study included one hundred fifty age-matched women. Table 1 shows a comparison of demographic parameters between case and control groups. Demographic characteristics including age, BMI, women’s occupation, use of pregnancy supplements, history of previous pregnancy and history of regular exercise were compared.

BMI: Body mass index
There was not a statistically significant between the case and control regarding women’s occupation (p>0.05). There was not a statistically significant between the case and control regarding use of pregnancy supplements, history of previous pregnancy, and history of regular exercise (p>0.05).

Table 2 shows comparison PSQI and SF-36 scores between case and control groups in detail. As stated in the table above, an Independent t-test did not find a statistically significant association between case and control in terms of PSQI score in pre-intervention (p>0.05). The PSQI score was similar for case and control groups (6.21 vs. 6.38). There was a statistically significant association was observed between the case and control regarding PSQI score in post-intervention (p<0.05). Women after pilates exercise had significantly higher sleep quality than controls (5.41 vs. 6.77). In Table 2, the comparison and examination of the sleep quality score separately before and after the intervention in each case and control group shows that the average sleep quality score before the intervention was insignificant between the control and intervention groups. However, after the intervention, the average sleep quality score of the case group was significantly lower than the score of the control group, and considering that in the PSQI, the total score is greater than six and shows the inappropriateness of the sleep quality, so it concluded that the case group experienced better sleep quality than the control group.

As stated in Table 2, a statistically significant association was observed between the case and control regarding the SF-36 score in post-intervention (p<0.05). The case group had significantly higher quality of life score than controls after the intervention 5.41±1.14 6.77±1.09 0.005. The PSQI score was similar for case and control groups in pre-intervention (p>0.05). The PSQI score was similar for case and control groups in post-intervention (p>0.05).

DISCUSSION

The present study, conducted to measure Pilates’ effect on the quality of sleep and life of pregnant women between the ages of 18-30, showed that regular Pilates exercise during the last months of pregnancy increases the quality of sleep and life in pregnant women. Meanwhile, in the present study, sleep quality decreased with the progress of pregnancy in the control group, and the quality of life remained unchanged.

Scholars have recently highlighted the significance of exercise for pregnant women. Our results were comparable to those of prior investigations that reported the positive impact of physical activities on pregnant women’s QoL and mental health. The details of physical activities and their positive impact are still essential and debatable topics among researchers. Liu et al. showed that group-based aerobic or resistance exercises increase the positive effects of these exercises on pregnant women’s QoL.

Ferraz et al. in a systematic review and meta-analysis, reviewed articles to evaluate the effect of pilates on the QoL of pregnant women. Based on the findings of this study, pilates exercises increase the QoL in pregnant women by reducing low-back pain. Mazzarino et al. reported regular pilates exercises to increase the QoL of low-risk pregnant women. They showed that this type of exercise is feasible for pregnant women and have small benefits for QoL, pain, and mobility.

The results were consistent with the present study. Contrary to the results of the present study, Gustafsson et al. showed that performing sports exercises for 24 sessions at home did not improve pregnant women’s QoL. In this study, unlike the current study, sports training did not improve the quality of life. The lack of alignment in the results of these studies can be due to the difference in sports training, intervention time, and lifestyle of the investigated community.

Azward et al. indicated the positive effect of yoga on improving sleep quality in the third trimester in pregnant women. Kocsis et al. showed the positive effect of gymnastics on the sleep quality of pregnant women during a designed 10-week exercise program. McCarthy et al. in a systematic review and meta-analysis, showed that different types of exercise during pregnancy improve sleep quality during pregnancy. Although the exercise type differed in these studies, the results were consistent with the present study. Hyun et al. reported that eight weeks of home-based tele-pilates exercise (50 min/day and twice a week) relieves pelvic and back pain and increases sleep quality during pregnancy. et al. suggested clinical Pilates exercises, including 18 positions, as a safe and effective method for reducing pain, disability and sleep problems in pregnant women. Insomnia in pregnant women is annoying, especially in the final months, and because the exact cause is unknown, regular Pilates exercises can be used for its treatment.

The main contribution of this study is to increase the quality of sleep and life in pregnant women. Reducing the quality of sleep and life is one of the most common problems in this period. The importance of physical activity during pregnancy is clear, but the details related to the number of exercises and their intensity should be considered more in research. This study investigated the effect of regular pilates exercises on pregnant women and reported its effects.
CONCLUSION

In view of the fact that the positive effects of Pilates exercises on the QoL and sleep reported in this study, it is possible to suggest Pilates during pregnancy to pregnant women. Insomnia and reduced quality of life in pregnant women profoundly affect them, and providing solutions without negative effects can be helpful. There is a need for more research on the subject with larger sample size.

ETHICAL DECLARATIONS

Ethics Committee Approval
This study was approved by Istanbul Medipol University Non-invasive Clinical Researches Ethics Committee (Date: 12.10.2023 Decision No: 839).

Informed Consent
All patients signed the free and informed consent form.

Referee Evaluation Process
Externally peer-reviewed.

Conflict of Interest Statement
The authors have no conflicts of interest to declare.

Financial Disclosure
The authors declared that this study has received no financial support.

Author Contributions
All of the authors declare that they have all participated in the design, execution, and analysis of the paper, and that they have approved the final version.
